

We never know the worth of water till the well is dry

The land we tread upon is one of the rarest of its kind. Earth is absolutely one of a kind as far as we know, but unfortunately far and few are people who can understand this. The planet is being ravaged by emissions and pollution and it doesn't seem it will stop any time soon.

Long gone are the days when the most emission-heavy machines were steam engines. There is pollution in every corner nowadays. What has happened? Several industrial revolutions later, we come to the present day. The world has improved and, as far as most of the world is concerned, life is actually getting better. But Earth is taking a beating in exchange for our lives becoming easier. The everlasting hunt for resources and notably oil has driven nations and corporations to devastate all corners of the world.

It's a shame. This planet is really one of a kind and there are none like it that we know of. Life itself is even rarer. But this actually stops absolutely nobody from causing damage to the only home we have ever known.

And for this negligence, we are suffering the consequences in the form of global warming and climate change. Our planet is seriously endangered as a result of our own technological advancement.

If this goes on any longer than it has to, we might not have a place to call home in the future. There is serious potential for humanity to end up destroying the very planet it started its life on. Will we sober in time or will the well run dry?
